

Machine Learning

Regularization

The problem of
overfitting

Example: Linear regression (housing prices)

$$\rightarrow \theta_0 + \theta_1 x$$

"Underfit" "High bias"

$$\rightarrow \theta_0 + \theta_1 x + \theta_2 x^2$$

"Just right"

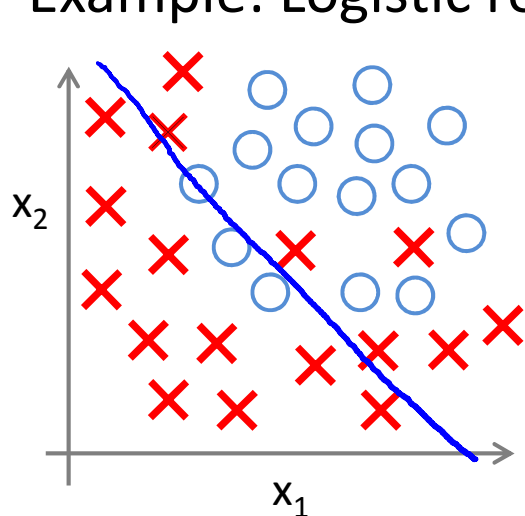

$$\rightarrow \theta_0 + \theta_1 x + \theta_2 x^2 + \theta_3 x^3 + \theta_4 x^4$$

"Overfit" "High variance"

Overfitting: If we have too many features, the learned hypothesis may fit the training set very well ($J(\theta) = \frac{1}{2m} \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)})^2 \approx 0$), but fail to generalize to new examples (predict prices on new examples).

Example: Logistic regression

$\rightarrow h_{\theta}(x) = g(\theta_0 + \theta_1 x_1 + \theta_2 x_2)$
 ($g = \text{sigmoid function}$)

"Underfit"

$g(\theta_0 + \theta_1 x_1 + \theta_2 x_2$
 $+ \theta_3 x_1^2 + \theta_4 x_2^2$
 $+ \theta_5 x_1 x_2)$

$g(\theta_0 + \theta_1 x_1 + \theta_2 x_1^2$
 $+ \theta_3 x_1^2 x_2 + \theta_4 x_1^2 x_2^2$
 $+ \theta_5 x_1^2 x_2^3 + \theta_6 x_1^3 x_2 + \dots)$

"Overfit"

Addressing overfitting:

x_1 = size of house

x_2 = no. of bedrooms

x_3 = no. of floors

x_4 = age of house

x_5 = average income in neighborhood

x_6 = kitchen size

⋮

x_{100}

Addressing overfitting:

Options:

1. Reduce number of features.
 - — Manually select which features to keep.
 - — Model selection algorithm (later in course).
2. Regularization.
 - — Keep all the features, but reduce magnitude/values of parameters θ_j .
 - Works well when we have a lot of features, each of which contributes a bit to predicting y .

Machine Learning

Regularization

Cost function

Intuition

Size of house

$$\theta_0 + \theta_1 x + \theta_2 x^2$$

Size of house

$$\theta_0 + \theta_1 x + \theta_2 x^2 + \cancel{\theta_3 x^3} + \cancel{\theta_4 x^4}$$

(Note: In the original image, pink arrows point to the θ_3 and θ_4 terms, and pink underlines are drawn under the θ_3 and θ_4 terms in the equation below.)

Suppose we penalize and make θ_3, θ_4 really small.

$$\rightarrow \min_{\theta} \frac{1}{2m} \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)})^2 + 1000 \theta_3^2 + 1000 \theta_4^2$$

(Note: In the original image, a blue underline is drawn under the entire cost function, and pink underlines are drawn under θ_3^2 and θ_4^2 .)

$$\theta_3 \approx 0 \quad \theta_4 \approx 0$$

(Note: In the original image, pink underlines are drawn under $\theta_3 \approx 0$ and $\theta_4 \approx 0$.)

Regularization.

Small values for parameters $\theta_0, \theta_1, \dots, \theta_n$

- “Simpler” hypothesis
- Less prone to overfitting

Housing:

- Features: x_1, x_2, \dots, x_{100}
- Parameters: $\theta_0, \theta_1, \theta_2, \dots, \theta_{100}$

$$J(\theta) = \frac{1}{2m} \left[\sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)})^2 + \lambda \sum_{j=1}^n \theta_j^2 \right]$$

~~$\theta_1, \theta_2, \theta_3, \dots, \theta_{100}$~~

Regularization.

$$\rightarrow J(\theta) = \frac{1}{2m}$$

$$\left[\sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)})^2 + \lambda \sum_{j=1}^n \theta_j^2 \right]$$

regularization parameter

$$\min_{\theta} J(\theta)$$

In regularized linear regression, we choose θ to minimize

$$J(\theta) = \frac{1}{2m} \left[\sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)})^2 + \lambda \sum_{j=1}^n \theta_j^2 \right]$$

What if λ is set to an extremely large value (perhaps far too large for our problem, say $\lambda = 10^{10}$)?

- Algorithm works fine; setting λ to be very large can't hurt it
- Algorithm fails to eliminate overfitting.
- Algorithm results in underfitting. (Fails to fit even training data well).
- Gradient descent will fail to converge.

In regularized linear regression, we choose θ to minimize

$$J(\theta) = \frac{1}{2m} \left[\sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)})^2 + \lambda \sum_{j=1}^n \theta_j^2 \right]$$

What if λ is set to an extremely large value (perhaps far too large for our problem, say $\lambda = 10^{10}$)?

$h_{\theta}(x)$

$$\theta_0 + \cancel{\theta_1 x} + \cancel{\theta_2 x^2} + \cancel{\theta_3 x^3} + \cancel{\theta_4 x^4}$$

$\theta_1, \theta_2, \theta_3, \theta_4$

$\theta_1 \approx 0, \theta_2 \approx 0$

$\theta_3 \approx 0, \theta_4 \approx 0$

$$h_{\theta}(x) = \theta_0$$

Regularized linear regression

$$J(\theta) = \frac{1}{2m} \left[\sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)})^2 + \lambda \sum_{j=1}^n \theta_j^2 \right]$$

$$\min_{\theta} J(\theta)$$

Regularized logistic regression.

$$h_{\theta}(x) = g(\theta_0 + \theta_1 x_1 + \theta_2 x_1^2 + \theta_3 x_1^2 x_2 + \theta_4 x_1^2 x_2^2 + \theta_5 x_1^2 x_2^3 + \dots)$$

Cost function:

$$\rightarrow J(\theta) = - \left[\frac{1}{m} \sum_{i=1}^m y^{(i)} \log h_{\theta}(x^{(i)}) + (1 - y^{(i)}) \log(1 - h_{\theta}(x^{(i)})) \right] + \frac{\lambda}{2m} \sum_{j=1}^n \theta_j^2$$

$\theta_1, \theta_2, \dots, \theta_n$

Avoiding Over-fitting

Tree Induction:

- Post-pruning
 - takes a fully-grown decision tree and discards unreliable parts
- Pre-pruning
 - stops growing a branch when information becomes unreliable

Linear Models:

- Feature Selection
- Regularization
 - Optimize some combination of fit and simplicity

Regularization

Regularized linear model:

$$\operatorname{argmax}_{\mathbf{w}} [\text{fit}(\mathbf{x}, \mathbf{w}) - \lambda * \text{penalty}(\mathbf{w})]$$

- “L2-norm”
 - The sum of the *squares* of the weights
 - L2-norm + standard least-squares linear regression = **ridge regression**
- “L1-norm”
 - The sum of the *absolute values* of the weights
 - L1-norm + standard least-squares linear regression = **lasso**
 - Automatic feature selection
