# Dynamic Time Warping Algorithm 

Slides from:

Elena Tsiporkova

## Shift variance

- Time series have shift variance
- Are these two points close?

## Time warp variance

- Slight changes in timing are not relevant - Are these two point close?

## Noise/filtering variance

- Small changes can look serious
- How about these two points?

## A real-world case

- Spoken digits

## Example data

$\xlongequal[\text { I }]{\text { I }} \frac{\mathrm{L}}{\text { UNIVERSITY OF ILLINOIS AT URBANA-CHAMPAIGN }}$

## Going from fine to coarse

- Small differences are not important
- Find features that obscure them

## A basic speech recognizer

- Collect template spoken words $T_{i}(t)$
- Get their DTW distances from input $x(t)$
- Smallest distance wins

## Clustering Time Series

- How do we cluster time series?
- We can't just use k-means ...
- We can use DTW for this

## Matching warped series

- Represent the warping with a path

$$
\mathbf{r}(i), i=1,2, \ldots, 6 \quad \mathbf{t}(j), j=1,2, \ldots, 5
$$

## Finding the overall "distance"

- Each node will have a cost

$$
\text { - e.g., } d(i, j)=\|\mathbf{r}(i)-\mathbf{t}(j)\|
$$

- Overall path cost is:

$$
D=\sum_{k} d\left(i_{k}, j_{k}\right)
$$

- Optimal $D$ path defines the "distance" between
 two given sequences

## Bellman's optimality principle

- For an optimal path passing through $(i, j)$ :

$$
\left(i_{0}, j_{0}\right) \xrightarrow{\text { opt }}\left(i_{f}, j_{f}\right)
$$

- Then:

$$
\begin{aligned}
& \left(i_{o}, j_{0}\right) \rightarrow\left(i_{f}, j_{f t}\right)= \\
& \left\{\begin{array}{l}
\text { opt } \\
\left.i_{0}, j_{0}\right) \rightarrow(i, j),(i, j) \rightarrow\left(i_{f}, j_{j}\right)
\end{array}\right\}
\end{aligned}
$$

## What is Special about Time Series Data?

Gene expression time series are expected to vary not only in terms of expression amplitudes, but also in terms of time progression since biological processes may unfold with different rates in response to different experimental conditions or within different organisms and individuals.

## Why Dynamic Time Warping?

Any distance (Euclidean, Manhattan, ...) which aligns the $i$-th point on one time series with the $i$-th point on the other will produce a poor similarity score.

A non-linear (elastic) alignment produces a more intuitive similarity measure, allowing similar shapes to match even if they are out of phase in the time axis.

## Warping Function

To find the best alignment between $\mathcal{A}$ and $\mathcal{B}$ one needs to find the path through the grid
$P=p_{1}, \ldots, p_{s}, \ldots, p_{k}$
$p_{s}=\left(i_{s}, j_{s}\right)$
which minimizes the total distance between them.
$P$ is called a warping function.

## Time-Normalized Distance Measure

Time-normalized distance between $\mathcal{A}$ and $\mathcal{B}$ :

$$
D(\mathcal{A}, \mathcal{B})=\left[\frac{\sum_{s=1}^{k} d\left(p_{s}\right) \cdot w_{s}}{\sum_{s=1}^{k} w_{s}}\right]
$$

$d\left(p_{s}\right)$ : distance between $i_{s}$ and $j_{s}$
$w_{s}>0$ : weighting coefficient.

Best alignment path between $\mathcal{A}$ and $\mathscr{B}$ :
$P_{0}=\underset{P}{\arg \min }(D(\mathcal{A}, \mathscr{B}))$.

## Optimisations to the DTW Algorithm

The number of possible warping paths through the grid is exponentially explosive!

- reduction of the search space

Restrictions on the warping function:

- monotonicity
- continuity
- boundary conditions
- warping window
- slope constraint.

## Restrictions on the Warping Function

Monotonicity: $\boldsymbol{i}_{s-1} \leq \boldsymbol{i}_{s}$ and $\boldsymbol{j}_{s-1} \leq \boldsymbol{j}_{s}$.
The alignment path does not go back in "time" index.

Guarantees that features are not repeated in the alignment.

Continuity: $\boldsymbol{i}_{s}-\boldsymbol{i}_{s-1} \leq 1$ and $\boldsymbol{j}_{s}-\boldsymbol{j}_{s-1} \leq 1$.
The alignment path does not jump in "time" index.

Guarantees that the alignment does not omit important features.

## Restrictions on the Warping Function

Boundary Conditions: $\boldsymbol{i}_{1}=1, \boldsymbol{i}_{\boldsymbol{k}}=\boldsymbol{n}$ and $j_{1}=1, j_{k}=m$.

The alignment path starts at the bottom left and ends at the top right.

Guarantees that the alignment does not consider partially one of the sequences.

Warping Window: $\left|\boldsymbol{i}_{s}-\boldsymbol{j}_{s}\right| \leq \boldsymbol{r}$, where $\boldsymbol{r}>0$ is the window length.

A good alignment path is unlikely to wander too far from the diagonal.

Guarantees that the alignment does not try to skip different features and gets stuck at similar features.

## Restrictions on the Warping Function

Slope Constraint: $\left(\boldsymbol{j}_{s_{p}}-\boldsymbol{j}_{s_{0}}\right) /\left(\boldsymbol{i}_{s_{p}}-\boldsymbol{i}_{s_{0}}\right) \leq \boldsymbol{p}$ and $\left(\boldsymbol{i}_{s_{q}}-\boldsymbol{i}_{s_{0}}\right) /\left(\boldsymbol{j}_{s_{q}}-\boldsymbol{j}_{s_{0}}\right) \leq \boldsymbol{q}$, where $\boldsymbol{q} \geq 0$ is the number of steps in the $x$-direction and $p \geq 0$ is the number of steps in the $y$ direction. After $\boldsymbol{q}$ steps in $\boldsymbol{x}$ one must step in $\boldsymbol{y}$ and vice versa: $\boldsymbol{S}=\boldsymbol{p} / \boldsymbol{q} \in[0, \propto]$.

The alignment path should not be too steep or too shallow.

Prevents that very short parts of the sequences are matched to very long ones.

## The Choice of the Weighting Coefficient

Time-normalized distance between $\mathcal{A}$ and $\mathscr{B}$ :

$$
D(\mathcal{A}, \mathscr{B})=\min _{P}\left[\frac{\sum_{s=1}^{k} d\left(p_{s}\right) \cdot w_{s}}{\sum_{s=1}^{k} w_{s}}\right] . \begin{gathered}
\text { complicates } \\
\text { optimisation }
\end{gathered}
$$

Seeking a weighting coefficient function which guarantees that:

$$
C=\sum_{s=1}^{k} w_{s}
$$

is independent of the warping function. Thus

$$
D(\mathcal{A}, \mathcal{B})=\frac{1}{C} \min _{P}\left[\sum_{s=1}^{k} d\left(p_{s}\right) \cdot w_{s}\right]
$$

Weighting Coefficient Definitions

- Symmetric form

$$
w_{s}=\left(\boldsymbol{i}_{s}-\boldsymbol{i}_{s-1}\right)+\left(\boldsymbol{j}_{s}-\boldsymbol{j}_{s-1}\right),
$$

$$
\text { then } C=n+m \text {. }
$$

- Asymmetric form

$$
w_{s}=\left(\boldsymbol{i}_{s}-\boldsymbol{i}_{s-1}\right),
$$

then $C=n$.
Or equivalently,
$w_{s}=\left(j_{s}-j_{s-1}\right)$,
then $C=m$.
can be solved by use of dynamic programming.

## Quazi-symmetric DTW Algorithm (warping window, no slope constraint)

## DTW Algorithm at Work

Start with the calculation of $\mathrm{g}(1,1)=\mathrm{d}(1,1)$.
Calculate the first row $\mathrm{g}(\boldsymbol{i}, 1)=\mathrm{g}(\boldsymbol{i}-1,1)+$ $\mathrm{d}(i, 1)$.

Calculate the first column $\mathrm{g}(1, \boldsymbol{j})=\mathrm{g}(1, \boldsymbol{j})+$ $\mathrm{d}(1, j)$.

Move to the second row $\mathrm{g}(i, 2)=\min (\mathrm{g}(i, 1)$, $\mathrm{g}(i-1,1), \mathrm{g}(\boldsymbol{i}-1,2))+\mathrm{d}(i, 2)$. Book keep for each cell the index of this neighboring cell, which contributes the minimum score (red arrows).

Carry on from left to right and from bottom to top with the rest of the grid $\mathrm{g}(i, j)=$ $\min (\mathrm{g}(i, j-1), \mathrm{g}(i-1, j-1), \mathrm{g}(i-1, j))+\mathrm{d}(i, j)$.

Trace back the best path through the grid starting from $\mathrm{g}(n, m)$ and moving towards $\mathrm{g}(1,1)$ by following the red arrows.

## DTW Algorithm: Example

| Time Series $\mathcal{A} \rightarrow$ | $\begin{aligned} & -0.87 \\ & -0.88 \end{aligned}$ | $\begin{aligned} & -0.84 \\ & -0.91 \end{aligned}$ | $\begin{aligned} & -0.85 \\ & -0.84 \end{aligned}$ | $\begin{aligned} & -0.82 \\ & -0.82 \end{aligned}$ | $\begin{aligned} & -0.23 \\ & -0.24 \end{aligned}$ | $\begin{aligned} & 1.95 \\ & 1.92 \end{aligned}$ | $\begin{aligned} & 1.36 \\ & 1.41 \end{aligned}$ | $\begin{aligned} & 0.60 \\ & 0.51 \end{aligned}$ | $\begin{aligned} & 0.0 \\ & 0.03 \end{aligned}$ | $\begin{aligned} & -0.29 \\ & -0.18 \end{aligned}$ |
